Inflammatory breast carcinoma: a review of 12 cases treated at Stanford University Medical Center. This retrospective analysis of 12 patients with metastatic inflammatory breast cancer treated at Stanford University Medical Center documents the outcomes of a recently introduced regimen consisting of paclitaxel, doxorubicin, and carboplatin. All patients were women with a median age of 52 years (range, 35 to 68). Five had stage IV disease, five had stage III disease, and two had stage II disease. All but one patient with stage IIIA

disease had initially undergone radical mastectomy. Paclitaxel, 175 mg/m², doxorubicin, 60 mg/m², and carboplatin, 300 mg/m², were administered every 3 weeks. Prior therapy consisted of local radiation (five patients), tamoxifen (five), and other agents (two). Granulocyte colony-stimulating factor was used as a support agent in six of nine patients (67%) with severe neutropenia. No patient had a complete response, and seven patients had progressive disease (six of whom had disease progression within 4 weeks after the initial cycle). No patient survived more than 15 months from diagnosis. Median survival was 2.6 months (range, 0.8 to 15.7). The most frequent toxicity was neutropenia, occurring in seven patients. Other toxicities included nausea and vomiting, anemia, and neuropathy. Neutropenic fever occurred in two patients. This study confirms the difficulty in treating patients with metastatic inflammatory breast cancer and shows that the response
